Abstract

Workplace harassment imposes substantial individual and organizational costs, yet the relative contributions of antagonistic "dark" traits and broader personality dimensions remain debated. This study examined how the HEXACO model—focusing on Honesty–Humility—adds to the prediction of harassment tendencies beyond the Dark Triad (Machiavellianism, narcissism, psychopathy) in Japanese adults. Participants completed the HEXACO-60, the SD3-J, and validated measures of power harassment and gender harassment. We reported Spearman correlations and multiple regressions with HC3 robust standard errors, and we evaluated incremental validity by adding HEXACO traits to Dark Triad–only models. Across models, psychopathy emerged as a consistent positive predictor of power harassment ($\beta \approx .32$–$.40$, $p<.001$), whereas Honesty–Humility showed a protective association ($\beta \approx -.14$, $\sim p=.05$), with Agreeableness additionally protective in sensitivity analyses ($\beta \approx -.17$, $p<.01$). For gender harassment, narcissism and psychopathy were positive predictors, while Honesty–Humility and Openness were negative predictors; notably, Machiavellianism displayed negative coefficients in adjusted models. Adding HEXACO traits increased explained variance beyond the Dark Triad ($\Delta R^2 \approx .032$, $p=.036$ for power harassment; $\Delta R^2 \approx .096$, $p<.001$ for gender harassment), indicating meaningful incremental validity—especially for gender harassment. Model diagnostics supported the use of robust inferences (non-normality/heteroskedasticity present; low multicollinearity; results stable after excluding high-influence cases). Findings underscore psychopathy as a central risk factor and Honesty–Humility as a cross-situational protective factor, suggesting that personnel risk assessment and harassment prevention in Japanese workplaces can benefit from integrating HEXACO—particularly Honesty–Humility—alongside dark-trait screening.

Introduction

Various tendencies of the Dark Triad

Narcissism, Machiavellianism, and Psychopathy, which constitute the Dark Triad, all share selfishness and a lack of empathy, yet they are distinguished by different psychological characteristics and behavioral tendencies (Paulhus & Williams, 2002). Narcissism is characterized by exaggerated self-love and a heightened sense of self-importance, along with a strong need for approval (Raskin & Terry, 1988; Morf & Rhodewalt, 2001). It is particularly notable for being motivated to maintain a grandiose self-image and to gain admiration from others (Campbell et al., 2002; Miller & Campbell, 2008). At the same time, while narcissism is associated with facets such as extraversion and potential leadership qualities (Paulhus, 2001; Brunell et al., 2008), it is also linked to hypersensitivity to criticism and aggressive reactions (Bushman & Baumeister, 1998; Thomaes et al., 2009). Machiavellianism is characterized by cold-bloodedness in manipulating others, long-term strategic thinking, and self-serving behaviors accompanied by moral flexibility (Christie & Geis, 1970; Wilson et al., 1996). This trait is tied to a desire for social dominance and pursuit of power (Jonason & Webster, 2010; Fehr et al., 1992), and is associated with a lack of empathy toward others and low moral concern (Jones & Paulhus, 2009; McHoskey, 1995). It also predicts higher levels of dishonesty and deceptive behavior in interpersonal relationships (Paulhus & Williams, 2002; Muris et al., 2017). Psychopathy is characterized by a lack of empathy and guilt, strong impulsivity, and a callous interpersonal attitude (Cleckley, 1941; Hare, 2003). This trait is deeply related to antisocial behaviors and norm violations (Hare, 1982; Lynam & Derefinko, 2006), and is known to be associated with high sensation-seeking and risk-taking behaviors (Zuckerman, 1994; Sellbom & Verona, 2007). Furthermore, it involves emotional blunting and ethical deviance (Blair, 2005; Glenn et al., 2009), and has been reported as one of the strongest predictors of aggression and violent tendencies (Hemphill et al., 1998; Neumann & Hare, 2008). Taken together, narcissism manifests as self-presentational and approval-seeking interpersonal behaviors, Machiavellianism as calculated and manipulative interpersonal engagement, and psychopathy as impulsive and antisocial behavioral patterns. However, they all share the common features of selfishness and lack of empathy (Paulhus & Williams, 2002; Vize et al., 2016), and are regarded as possessing characteristics strongly contrasting with the Honesty–Humility factor of the HEXACO model (Lee & Ashton, 2005; Ashton & Lee, 2007). Because these three traits share a common core of selfishness and lack of empathy, in workplaces where power, norms, and rewards intersect, they may, albeit through different pathways, converge into deviant behaviors such as bullying, abusive supervision, and misconduct.

The Dark Triad and workplace tendencies

The traits of the Dark Triad, through distinct pathways, are linked to deviant behaviors such as workplace bullying, abusive supervision, and counterproductive work behaviors (CWB), thereby becoming major factors that undermine organizational functioning and employee well-being (LeBreton et al., 2018; O'Boyle et al., 2012; Pletzer et al., 2019a; Miao et al., 2023; Robinson &

Bennett, 1995; Lee, Ashton, & de Vries, 2005; Ashton & Lee, 2008). Workplace bullying refers to repeated and continuous harmful behaviors, while abusive supervision denotes sustained verbal and non-physical hostility from supervisors toward subordinates (Tepper, 2000).

First, psychopathy, with its clinical characteristics of callousness, lack of empathy, diminished sense of guilt, and impulsivity, has been associated with abusive supervision, destructive leadership, and authoritarian "petty tyrant" behaviors, which in turn reduce employees' job satisfaction and mental health (Hare & Neumann, 2008; Boddy, 2011; Mathieu et al., 2013; Tepper, 2000; Einarsen et al., 2007; Ashforth, 1994; Babiak & Hare, 2006). Furthermore, poor sleep quality among leaders and deficits in emotional intelligence have been shown to facilitate aggressive behaviors and daily abusive supervision (Barnes et al., 2015; Van et al., 2022; Salovey & Mayer, 1990; Cherniss & Goleman, 2001), and vulnerabilities have also been reported whereby harassment more readily emerges and persists in contexts of laissez-faire or deviant leadership (Tsuno & Kawakami, 2015; Skogstad et al., 2007). Machiavellianism, characterized by cold manipulation of others, strategic thinking, and instrumental interpersonal orientation accompanied by moral flexibility, is associated with reduced organizational citizenship behaviors (OCB) and bullying perpetration through interpersonal exploitation and self-serving decision-making (Christie & Geis, 1970; Zettler & Solga, 2013; Baughman et al., 2012; Dåderman & Ragnestål-Impola, 2019). Together with distortions of cognition related to gender roles, it has also been linked to heightened tendencies toward sexual harassment (Zeigler-Hill et al., 2016; Jonason et al., 2012; Jones & Paulhus, 2010), and its harmfulness has been consistently confirmed as a predictor of CWB and norm violations (O'Boyle et al., 2012; Lee et al., 2005). Narcissism, with its grandiosity, sense of entitlement, and excessive need for admiration, manifests as interpersonal dominance and a focus on nominal achievements, and in top management is associated with striking but volatile decisions such as strategic dynamism and grandiose tendencies in mergers and acquisitions (Chatterjee & Hambrick, 2007). At the same time, it has also been linked to aggression in ego-threatening situations, tendencies toward sexual coercion, and CWB (Bushman et al., 2003; Grijalva & Newman, 2015; O'Boyle et al., 2012), overlapping with social manipulativeness that promotes short-term mating strategies and opportunistic interpersonal behaviors (Jonason et al., 2009; Jones & Paulhus, 2010). From an integrative perspective, although the pathways and manifestations of each Dark Triad trait differ, they converge on diverse deviant behaviors such as bullying, abusive supervision, misconduct, and sexual harassment, and they share the common feature of negatively impacting workplace safety, health, engagement, and retention (LeBreton et al., 2018; O'Boyle et al., 2012; Zeigler-Hill et al., 2016; Mathieu et al., 2013). Conversely, within the HEXACO framework, Honesty–Humility has been shown to be a powerful suppressor of such deviant behaviors, suggesting that the model may offer superior explanatory power for workplace deviance compared to the Big Five (Pletzer et al., 2019a; Lee et al., 2019; Ashton & Lee, 2008; Lee et al., 2005; Ashton et al., 2014).

HEXACO in personality research

The HEXACO model is a six-factor structure derived from factor analyses of personality descriptions based on lexical studies, and by introducing the dimensions of Honesty–Humility, Emotionality, Extraversion, Agreeableness, Conscientiousness, and Openness to Experience, it extends the traditional Big Five while presenting a trait space with greater independence (Ashton & Lee, 2007; Ashton et al., 2004; Thielmann et al., 2021). First, Honesty–Humility is a dimension centered on ethical tendencies such as sincerity, fairness, greed avoidance, and modesty, and it provides a framework for explicitly measuring individual differences in anti-egoistic and anti-manipulative tendencies that were insufficiently captured by the Five-Factor Model (FFM) (Ashton & Lee, 2007; Ashton et al., 2014). Its uniqueness is further supported by meta-analytic evidence that the explanatory power of the Big Five is limited (Thielmann et al., 2021; Howard & Van Zandt, 2020). Moreover, strong negative associations with the "dark" traits that counteract self-enhancement and the pursuit of resources and advantage have been consistently reported, suggesting the distinctiveness of the HEXACO moral dimension (Lee et al., 2013; Moshagen et al., 2018). Emotionality encompasses anxiety, sensitivity to threat, dependence, and sentimentality, but it is a reconceptualization that separates the anger component from Neuroticism in the FFM (Ashton & Lee, 2007; Ashton & Lee, 2009). Cross-cultural studies have repeatedly confirmed that women score relatively higher on this dimension (Costa et al., 2001; Schmitt et al., 2008), and meta-analyses at the scale level have demonstrated high internal consistency and self–other agreement (Moshagen et al., 2019; Morales, 2020). Extraversion is characterized by social self-esteem, boldness, sociability, and liveliness (Ashton & Lee, 2007; Ashton & Lee, 2009). While it corresponds strongly to extraversion in the FFM, within the highly orthogonal structure of HEXACO it is repositioned as a core component involving interpersonal energy and reward sensitivity (Thielmann et al., 2021). Differentiation from subordinate features such as intellectual engagement and dominance has been shown to increase the granularity of behavioral prediction (Anglim et al., 2022; Zettler et al., 2020). Agreeableness, centered on tolerance, gentleness, patience, and forgiveness, is redefined by

incorporating anger-related tendencies that were included on the side of Neuroticism in the FFM (Ashton & Lee, 2007; Thielmann et al., 2021). By emphasizing interpersonal regulatory functions such as low aggressiveness and low propensity for revenge, it captures more precisely the individual differences in behavioral restraint and tolerance in conflict situations (Ashton et al., 2014; Zettler et al., 2020). Conscientiousness forms the core of self-regulation, encompassing orderliness, diligence, perfectionism, and prudence (Ashton & Lee, 2007; Ashton & Lee, 2009). Reflecting long-term goal orientation and the discipline of error avoidance, it has been shown in reviews and meta-analyses to contribute reliably to the prediction of a wide range of important outcomes (Ozer & Benet-Martínez, 2006; Zettler et al., 2020). Comparative studies across models have also confirmed an extremely strong correspondence with Conscientiousness in the FFM (Thielmann et al., 2021). Openness to Experience, based on aesthetic sensitivity, inquisitiveness, creativity, and unconventionality, reflects intellectual curiosity and the breadth of value orientation (Ashton & Lee, 2007; Ashton & Lee, 2009). Associations have been confirmed with crystallized intelligence, worldviews, and attitudes (Anglim et al., 2022; Lee, Ashton, Ogunfowora, Bourdage, & Shin, 2010). While maintaining high correspondence with Openness in the FFM, it clarifies individual differences in cognitive flexibility and value orientation within the independent structure of HEXACO as a whole (Thielmann et al., 2021; Lee, Ashton, Griep, & Edmonds, 2018). Taken together, while HEXACO shows high correspondence with the FFM, the introduction of Honesty–Humility and the reorganization of Agreeableness and Emotionality position it as a comprehensive model that expands both the scope of explanation and the orthogonality of dimensions in understanding and predicting social and moral behavior (Ashton & Lee, 2007; Thielmann et al., 2021; Zettler et al., 2020). In particular, Honesty–Humility occupies a theoretical focal point as the inverse trait of the Dark Triad, and the following section will provide an overview of how each dimension of HEXACO predicts actual workplace behaviors such as leadership, OCB/CWB, satisfaction, and turnover intentions.

HEXACO and workplace behaviors

The HEXACO model has accumulated evidence as a powerful framework for explaining a wide range of workplace behaviors—such as the preference for and enactment of leadership, organizational citizenship behavior (OCB) and counterproductive work behavior (CWB), work engagement and burnout, job satisfaction, performance, turnover intentions, attitudes toward diversity, and even measurement approaches in personnel selection. Studies have demonstrated that not only domain-level but also facet-level examinations can enhance predictive validity, that facets such as fairness and diligence are particularly important, and that person–leader fit as well as contextualized assessments (e.g., situational judgment tests, SJTs) have proven useful (Ashton & Lee, 2007; Pletzer et al., 2021; Breevaart & de Vries, 2019). Honesty–Humility, reflecting characteristics such as sincerity, fairness, low greed, and restrained status-seeking, has consistently been shown to strongly suppress workplace deviance, misconduct, and abuse, and to be associated with ethical, servant, and democratic leadership (Ashton & Lee, 2007; Pletzer et al., 2019b; Pletzer et al., 2021). Measurement of HEXACO through SJTs has revealed associations between Honesty–Humility and supervisor-rated OCB, suggesting its potential as an indicator of selection validity (Oostrom et al., 2019; Lee et al., 2005; Breevaart & de Vries, 2017). Emotionality, which includes tendencies toward anxiety, dependence, and sentimentality, is related to the risk of burnout and vulnerability to stressors (Maslach & Leiter, 2016; Bianchi, 2018; Răducu & Stănculescu, 2022). This finding is consistent with evidence that followers sensitive to interpersonal safety and care orientation prefer relationship-oriented or task-oriented leaders (Shamir et al., 1993; Breevaart & de Vries, 2021; Hoch et al., 2018). Extraversion, supported by high energy, assertiveness, and sociability, promotes extra-role contributions and team involvement (Pletzer et al., 2021; Anglim et al., 2018), underpins vigor, dedication, and absorption as the core of work engagement (Schaufeli et al., 2002; Inceoglu & Warr, 2011), and is associated with preferences for charismatic leadership (Bass, 1990; Breevaart & de Vries, 2021; Conger, 1999). Agreeableness, reflecting interpersonal adaptability such as tolerance, gentleness, and avoidance of revenge, has consistently been shown to suppress CWB and enhance OCB, to be inversely related to deteriorating abusive and authoritarian relationships, and to be positively associated with democratic, servant, and authentic leadership behaviors (Pletzer et al., 2019b; Pletzer et al., 2021; Zettler et al., 2020; Gandolfi et al., 2017; Breevaart & de Vries, 2019). Furthermore, evidence indicates that tendencies toward workplace harassment perpetration are linked to low agreeableness (Tepper, 2000; De Hoogh & Den Hartog, 2008). Conscientiousness, based on self-control, diligence, and adherence to norms, reliably predicts task performance and productivity, enhances OCB, and suppresses CWB, making it one of the most powerful traits for these outcomes (Barrick & Mount, 1991; Pletzer et al., 2021; Pletzer et al., 2019b). It also extends broadly to job satisfaction, safety compliance, and error reduction (Wright & Cropanzano, 2000; Wallace & Vodanovich, 2003; Lee et al., 2005). Openness to Experience, as a resource of intellectual curiosity, creativity, and novelty seeking, is positively associated with OCB (Pletzer et al., 2021; Thielmann et al., 2020), relates to preferences for and acceptance of transformational and charismatic leadership (Judge & Bono, 2000; Breevaart & de Vries, 2021), and supports positive attitudes

toward organizational diversity and adaptive learning (Anglim et al., 2019; Schwartz, 1992; Lee & Ashton, 2004). Such synergistic effects of domain traits are reflected in specific workplace outcomes: extraversion, conscientiousness, and agreeableness consistently support job satisfaction and performance; Honesty–Humility maintains organizational functioning through high ethicality and low deviance; Emotionality relates to stress responses and exhaustion management (Saltuküğlu et al., 2019; Ashton & Lee, 2007; Maslach & Leiter, 2016). In particular, democratic leadership corresponds with Honesty–Humility and Conscientiousness, supportive relationships correspond with Agreeableness, and charismatic influence corresponds with Extraversion and Openness—a pattern of "contextualized personality–leadership behavior correspondence" that has been demonstrated both theoretically and empirically (de Vries, 2012; Breevaart & de Vries, 2019; Judge & Bono, 2000). From a human resource practice perspective, the development and validation of SJTs based on HEXACO have demonstrated that personality traits, including Conscientiousness and Honesty–Humility, relate to OCB and selection outcomes while compensating for the limitations of self-report measures (e.g., social desirability, faking). When combined with facet-level evaluations, they allow for more precise predictions of deviance suppression and promotion of citizenship behaviors (Oostrom et al., 2019; McDaniel et al., 2007; Christian et al., 2010; Pletzer et al., 2021). Furthermore, HEXACO traits are also implicated in career turnover intentions and actual turnover: Extraversion and Openness are linked to change orientation, Conscientiousness and Agreeableness promote retention, and individuals high in Dark Triad traits are more likely to exhibit turnover intentions. Perceived organizational support (POS) particularly enhances engagement when coupled with Extraversion and Conscientiousness (Zimmerman, 2008; Woo, 2011; Rhoades & Eisenberger, 2002; Machiha & Brew, 2019). Taken together, HEXACO is a model that transcends leadership (preference/enactment), OCB, CWB, job satisfaction, job performance, turnover intentions, diversity attitudes, health-related indicators (burnout), and measurement/selection as essential aspects of the workplace. In particular, Honesty–Humility, Conscientiousness, Agreeableness, and Extraversion support desirable behaviors through the four functional axes of "ethics/norm compliance—productivity—relationships—vitality." Emotionality contributes to the management of stress vulnerability, and Openness facilitates learning, innovation, and diversity acceptance, thereby forming a coherent picture supported consistently across theory and practice (Ashton & Lee, 2007; Pletzer et al., 2021; Anglim et al., 2019; Răducu & Stănculescu, 2022).

Dark Triad research in Japan

The foregoing discussion suggests that, while the integration of HEXACO and the Dark Triad is effective for understanding workplace behaviors, the modes of expression and effect sizes may vary depending on cultural context. Accordingly, this section provides an overview of the accumulation of Dark Triad research in Japan and its cultural characteristics, and organizes issues relevant for subsequent hypothesis formulation. In Japan, Dark Triad research has progressed on the basis of the development of measurement scales and examination of cultural validity, with empirical investigations using domestic data advancing across specific phenomena. Beginning with the Japanese adaptation of short-form scales (Tamura et al., 2015; Shimotsukasa & Oshio, 2017), discussions attentive to measurement equivalence and cultural differences have accompanied these developments (Byrne & Campbell, 1999; van de Vijver & Leung, 2000; Schmitt et al., 2007). Regarding Machiavellianism, repeated findings have demonstrated its connection with manipulative strategies such as "persuasion, ingratiation, and self-disclosure" (Shimotsukasa & Oshio, 2019; Tada & Oshio, 2018). It has also been widely reported to be associated with interpersonal aversion and avoidance of being disliked (Koshinaka, 2020), has been linked to tendencies toward gambling disorder (Takada, 2023), and has been shown to align with low Agreeableness and low Honesty–Humility within the frameworks of the FFM and HEXACO (Kiire, 2016). Regarding psychopathy, classical characteristics such as lack of empathy and dominant, aggressive manipulation have been summarized in domestic reviews (Masui & Ura, 2018). Findings have shown associations with interpersonal aversion, avoidance of being disliked, and gender differences (Koshinaka, 2020). A proposed model indicates that psychopathy directly increases loneliness while also exerting effects indirectly via experiences of social exclusion (Tomii & Oshio, 2024). Empathy tasks using photographs of expressed emotions suggest fluctuations in these associations depending on gender (Fukui et al., 2017, 2018), and psychopathy has also been shown to be linked to both self-enhancing and self-deprecating manipulative strategies (Shimotsukasa & Oshio, 2019). Regarding narcissism, domestic reviews have noted its duality, being rooted in superiority maintenance and the need for admiration, while potentially having adaptive aspects depending on the situation (Masui & Ura, 2018). Findings have indicated that narcissism weakens interpersonal aversion and is positively associated with respect and affection (Koshinaka, 2020), that it exerts a negative direct effect on loneliness and also suppresses the impact of exclusion experiences (Tomii & Oshio, 2024), and that in the context of strategic interpersonal behaviors it may connect with short-term mating strategies through mate retention behaviors (Kiire & Ochi, 2017). In the adaptive behavioral domain of everyday prosociality, it has also been shown that contributions of the Dark Triad as a whole are limited in Japanese samples (Oda & Matsumoto-Oda, 2022). Taken together, domestic research on the

Dark Triad has expanded into multiple domains such as manipulative strategies, interpersonal emotions, gambling, mate strategies, and prosociality. While considering the implications of overseas meta-analyses on workplace behaviors (O'Boyle et al., 2012), systematic examination of direct associations with workplace harassment in Japan remains limited. Future research must therefore pursue longitudinal and context-dependent investigations that integrate HEXACO—particularly Honesty–Humility—while paying careful attention to measurement equivalence.

Purpose of the study

The purpose of the present study is to clarify how the Dark Triad traits (narcissism, Machiavellianism, and psychopathy) are related to harassment tendencies among Japanese adults, and further to examine how the traits of the HEXACO model influence these relationships. In particular, the main focus is to determine the extent to which Honesty–Humility, the core dimension of HEXACO, can suppress harassment tendencies. Moreover, by analyzing the Dark Triad and HEXACO simultaneously, this study also aims to assess the degree to which HEXACO possesses incremental explanatory power compared to the Dark Triad. As for the analytical methods, correlation analyses will first be employed to identify the simple associations between each trait and harassment tendencies, followed by multiple regression analyses to examine whether the HEXACO dimensions retain unique predictive power even when controlling for the influence of the Dark Triad. Through this approach, the study seeks to verify whether the previously established finding that the Dark Triad is positively associated with harassment tendencies can be replicated in Japanese data, and to empirically demonstrate whether Honesty–Humility functions as a strong suppressor. The significance of this study is threefold. First, it connects the consistently reported associations between the Dark Triad and workplace deviance in overseas meta-analyses to the Japanese cultural context, thereby elucidating cultural differences in effect sizes and pathways. Second, by introducing HEXACO, it is expected to make an academic contribution by demonstrating that individual differences in morality and anti-egoism—which could not be sufficiently explained by the traditional Big Five—contribute to the understanding of harassment tendencies in Japan. Third, in practical terms, this study can provide concrete implications for the prevention of harassment and the formation of a healthy organizational culture by utilizing the HEXACO framework, including Honesty–Humility, in recruitment, personnel placement, and the development of managerial staff.

Methods

Research Design and Implementation

This study was conducted as a cross-sectional survey. Data collection was carried out online using Google Forms as the response platform. The main analyses were rank correlations and multiple regressions, and the regression estimates adopted HC3 robust standard errors to account for non-normality and heteroscedasticity.

Participants

Participants were recruited through crowdsourcing, and 380 individuals responded. Based on predefined criteria, inattentive responses (e.g., selecting the same option consecutively, extremely short or long response times) and duplicate responses were excluded. A final sample of 354 participants was analyzed. Of these, 134 were men and 220 were women. The age distribution was: 32 participants aged 18–19, 100 in their 20s, 124 in their 30s, 70 in their 40s, and 28 aged 50 or older. Due to the design of Google Forms, all items were mandatory, and therefore missing responses did not occur. In the actual dataset, a small number of technical missing values were observed in certain indicators (at most less than 0.3%), but complete-case analysis indicated that the impact on results was negligible.

Ethical Considerations

Participants were provided with explanations regarding the purpose of the study, procedures, privacy protection, voluntary participation and the right to withdraw, and dissemination of results. Informed consent was obtained from all participants. Collected data were anonymized and stored securely. The study was approved by the Institutional Review Board of the Public Health Research Foundation (Reference no.25G0001).

Measurement Instruments

Personality traits were measured using the Japanese version of the HEXACO-60, which assesses six factors: Honesty–Humility, Emotionality, Extraversion, Agreeableness, Conscientiousness, and Openness (Wakabayashi, 2014). The Dark Triad was assessed with the Japanese version of the Short Dark Triad (SD3-J), consisting of Machiavellianism, Narcissism, and Psychopathy (Shimotsukasa & Oshio, 2017). Harassment tendencies were measured with the Workplace Power Harassment Scale (Tou et al., 2017) and the Gender Harassment Scale (Kobayashi & Tanaka, 2010–2011). Previous studies have reported sufficient internal consistency: Cronbach's α = .72–.84 for HEXACO factors, α ≥ .70 for each SD3-J subscale, α ≈ .80 for the two subscales of the Gender Harassment Scale, and α = .802–.875 for the three subscales (behavior, state, and attitude) of the Power Harassment Scale.

Procedure

The survey was conducted from August 1 to August 18, 2025. The order of responses was HEXACO, SD3-J, Power Harassment, and Gender Harassment. Participants received Amazon gift cards as compensation.

Data Processing

Since the data were collected in a mandatory-response format, no missing values were present. Minor technical missing values (less than 0.3%) were handled by listwise deletion. For preprocessing, continuous variables included in regression analyses were z-standardized (mean = 0, standard deviation = 1) to ensure interpretability of standardized regression coefficients (β). Categorical variables such as gender and region were dummy-coded, and reference categories were set. Outliers and distributional properties were checked as part of regression diagnostics, including residual normality (Shapiro–Wilk), autocorrelation (Durbin–Watson), and heteroscedasticity (Breusch–Pagan). Influential observations were identified using Cook's distance with a threshold of >4/n. Multicollinearity was assessed with the Variance Inflation Factor (VIF), applying general cutoffs (5–10).

Analytical Strategy

All analyses were conducted in Python (pandas, statsmodels, SciPy). We first computed Spearman rank correlations among all focal variables to accommodate skewed distributions and potential outliers. For prediction, we estimated a series of multiple regression models with HC3 robust standard errors; effect sizes are reported as standardized coefficients (β), and two-tailed tests were used with ***$p < .001$, **$p < .01$, *$p < .05$.

Model definitions:

- Model A = controls (age, gender, region) + Dark Triad (Machiavellianism, Narcissism, Psychopathy).
- Model B = Model A + HEXACO (six factors).
- Model C = Model B + interactions between Honesty–Humility (H–H) and each Dark Triad trait.

Primary inference and incremental validity: Harassment tendencies (power harassment, gender harassment) were the primary outcomes. We emphasize Model B coefficients for substantive interpretation (see Table 3: B_controls+DT+HEXACO), and we evaluate the added value of HEXACO via $\Delta R^2 = R^2(B) - R^2(A)$ and corresponding F-tests (see Table 4). To probe moderation, Model C added H–H × Dark Triad interactions; when incremental fit over Model B was negligible, we report this succinctly (see Table 4).

Sensitivity and stratified analyses: As a sensitivity analysis, we re-estimated Model B after excluding high-influence observations using Cook's distance > 4/n (see Table 4). For diagnostics, see Table 6a; VIFs are in Table 6b. For gender-stratified evidence, we fit Model B separately for men and women and compare explained variance and key coefficients (see Table 5; coefficients also summarized in Table 3: B_by_gender).

Diagnostics and multicollinearity: We inspected distributional and heteroskedasticity diagnostics and relied on HC3 for inference. Multicollinearity was assessed via variance inflation factors; VIF results are reported in Table 6b.

Summary of Model Diagnostics

Model diagnostics included checks of residual normality (Shapiro–Wilk test), autocorrelation (Durbin–Watson statistic), heteroscedasticity (Breusch–Pagan test), and influential cases (Cook's distance, with a threshold of 4/n). Multicollinearity was

assessed using variance inflation factors (VIF), with commonly used cutoffs (5–10). Robust standard errors were adopted to address violations of normality or heteroscedasticity, and sensitivity analyses were conducted to ensure the robustness of the results. Final models were selected with an emphasis on interpretability.

Software and Reproducibility

Analyses were conducted with Python 3.12.3. Reproducible scripts and model outputs (correlation tables, regression coefficients, diagnostic statistics, VIF lists) can be provided as appendices or in a repository, with access conditions specified in the Data Availability section. No procedures requiring random seeds were employed.

Results

Descriptive Statistics

Table 1 presents descriptive statistics for the primary variables. Mean scores (SDs) for the HEXACO factors were Honesty–Humility (H–H) 3.25 (0.59), Emotionality (E) 3.30 (0.78), Extraversion (X) 2.70 (0.84), Agreeableness (A) 2.88 (0.73), Conscientiousness (C) 3.21 (0.68), and Openness (O) 3.46 (0.80). For the Dark Triad, means (SDs) were Machiavellianism 3.58 (0.66), Narcissism 2.40 (0.72), and Psychopathy 2.50 (0.66). Harassment tendencies averaged 1.26 (0.32) for power harassment and 1.70 (0.70) for gender harassment. The sample spans a broad age range and includes adequate numbers of both men and women.

Correlation Analysis

Spearman rank correlations among HEXACO, Dark Triad traits, and harassment tendencies are shown in Table 2. H–H correlated negatively with Machiavellianism ($\rho = -.32$, $p < .001$), Narcissism ($\rho = -.36$, $p < .001$), and Psychopathy ($\rho = -.38$, $p < .001$), and also with power harassment ($\rho = -.23$, $p < .001$) and gender harassment ($\rho = -.18$, $p < .001$). Agreeableness correlated negatively with Machiavellianism ($\rho = -.27$, $p < .001$), Psychopathy ($\rho = -.36$, $p < .001$), and power harassment ($\rho = -.26$, $p < .001$). By contrast, Extraversion correlated positively with Narcissism ($\rho = .56$, $p < .001$), Psychopathy ($\rho = .16$, $p < .01$), and gender harassment ($\rho = .11$, $p < .05$). Overall, these patterns suggest that H–H/A may be suppressive while X may be facilitative in some contexts.

Multiple Regression Analysis

We conducted hierarchical regressions predicting power and gender harassment. Model A included controls (age, gender, region) and the Dark Triad; Model B additionally included the six HEXACO factors. Below we report standardized β with HC3-robust p-values (coefficients = Table 3; model comparison = Table 4). For interpretation, we treat $|\beta| \approx .10$ as small, $\approx .20$ as modest, $\approx .30$ as a practically meaningful medium effect, and $\geq .50$ as large; in this literature, even $\Delta R^2 \approx .02–.03$ can be policy-relevant. Power harassment. In Model A, only Psychopathy was significant ($\beta = .396$, $p < .001$), whereas the other Dark Triad traits were not (M: $\beta = -.062$, $p = .342$; N: $\beta = -.005$, $p = .933$). In Model B, R^2 increased from .166 to .198, with $\Delta R^2 = .032$, F change = 2.28, $p = .036$. Key predictors in Model B were Psychopathy ($\beta = .317$, $p < .001$) and H–H ($\beta = -.143$, $p = .049$); Agreeableness was marginal ($\beta = -.108$, $p = .063$) (Tables 3–4). Gender harassment. In Model A, Machiavellianism ($\beta = -.138$, $p = .006$), Narcissism ($\beta = .180$, $p < .001$), and Psychopathy ($\beta = .165$, $p = .004$) were all significant. In Model B, R^2 rose from .117 to .213, with $\Delta R^2 = .096$, F change = 6.91, $p < .001$. H–H ($\beta = -.230$, $p < .001$) and Openness ($\beta = -.236$, $p < .001$) were negative predictors, while Dark Triad effects remained (M: $\beta = -.164$, $p = .003$; N: $\beta = .190$, $p = .004$; P: $\beta = .154$, $p = .009$). Gender was also significant ($\beta = -.312$, $p = .006$; coded 0=male, 1=female; the negative sign indicates higher scores among men).

Sensitivity Analysis and Interaction Effects

Re-estimating Model B after removing cases with Cook's distance > 4/n yielded R^2 B sensitivity of .221 (power harassment) and .203 (gender harassment), indicating that main findings were largely preserved (details = Table 4; max Cook's D = 0.058/0.043; exceedances = 23/15). Adding H–H × M/N/P interactions produced R^2 with interactions of .218 (power) and .219 (gender), representing only small improvements over Model B (Table 4).

Gender-Stratified Analyses

When Model B was estimated separately by gender, R^2 was higher in the gender-0 group (Table 5). For power harassment: gender-0 .287 (n = 133) vs. gender-1 .203 (n = 220); for gender harassment: gender-0 .283 (n = 133) vs. gender-1 .166 (n = 220). While these differences may reflect variation in effect sizes and compositions across groups, sample size and measurement error should also be considered.

Model Diagnostics

Durbin–Watson statistics were 1.95 (power) and 1.84 (gender), suggesting little residual autocorrelation. Shapiro–Wilk and Breusch–Pagan tests were significant, indicating deviations from normality and homoscedasticity; inference therefore relies on HC3 robust SEs (Table 6a). VIFs were modest (max 2.00 for N; mean 1.40), implying no serious multicollinearity (top values: N = 2.00, X = 1.70, H–H = 1.57; Table 6b). Missingness was minimal (each Dark Triad variable 0.28%; others 0%), yielding an effective sample of n = 353.

Discussion

Summary of Results

This study examined the associations among HEXACO traits, Dark Triad traits, and harassment tendencies in a Japanese sample. As a result, it was confirmed that Honesty–Humility consistently served as a negative predictor for all Dark Triad traits. In addition, Agreeableness was also negatively related to Machiavellianism and Psychopathy, indicating that the interpersonally adaptive traits of the HEXACO model suppress Dark Triad tendencies. On the other hand, Extraversion positively predicted Narcissism and Psychopathy, suggesting that the interpersonal orientation aspect of HEXACO traits may be linked to certain Dark Triad traits. Furthermore, analyses concerning harassment tendencies revealed that low levels of Honesty–Humility and Agreeableness predicted power harassment, while low levels of Honesty–Humility and Openness predicted gender harassment. Gender also had a significant effect on gender harassment, with men showing higher tendencies. These findings suggest that HEXACO traits may function as inhibitory factors for harassment behaviors in the context of Japanese workplace environments.

Theoretical Implications

The results of this study support previous findings that demonstrated the associations between the HEXACO model and the Dark Triad, now replicated in a Japanese sample. In particular, Honesty–Humility has repeatedly been identified as a predictor of malicious and exploitative behaviors in interpersonal relationships, and this study likewise showed that it acts in a direction that suppresses both Dark Triad traits and harassment tendencies. This provides evidence for the theoretical strength of the HEXACO model—namely, that Honesty–Humility, which is not included in the Big Five, is indispensable for explaining socially deviant behaviors. Moreover, the finding that Extraversion was positively associated with Narcissism and Psychopathy indicates that the interpersonal orientation inherent in Extraversion does not necessarily function adaptively but may, in some cases, be linked to self-centeredness and risk-taking tendencies. In addition, the observation that Dark Triad traits were associated with harassment tendencies even in a Japanese sample is consistent with findings from Western cultural contexts, suggesting that these associations may replicate across cultures. Furthermore, the significant gender effect in gender harassment implies that gender norms and workplace culture in Japanese society may be influencing these outcomes, highlighting the need for a theoretical framework that takes cultural factors into account. Notably, Machiavellianism turned negative for gender harassment in multivariate models, consistent with a suppression pattern after controlling shared antagonistic variance with Narcissism and Psychopathy.

Practical Implications

The findings of this study provide concrete implications for harassment prevention and human resource management in Japanese workplaces. First, since HEXACO traits such as Honesty–Humility and Agreeableness act in the direction of suppressing harassment tendencies, measuring and evaluating these traits may be useful for predicting potential risks at the stages of recruitment and promotion. For example, by introducing assessments based on the HEXACO model in personnel selection and placement, it would be possible to identify interpersonal risks within the organization in advance. From the perspective of education and training, considering that low levels of Honesty–Humility are strongly associated with Dark Triad traits and harassment behaviors, it would be effective to develop training programs that emphasize humility and ethical awareness.

Particularly in Japanese workplace culture, where hierarchical relationships and group harmony tend to be strongly emphasized, abuse of power and the imposition of gender norms are likely to lead to harassment. Therefore, designing individualized interventions based on employees' personality traits may be more effective than uniform training programs. Furthermore, the finding that Extraversion was associated with Narcissism and Psychopathy points to an important consideration in leadership evaluation and promotion. While superficial sociability and confidence are often regarded as desirable qualities for organizations, when these traits are linked to self-centeredness and aggressive tendencies, harassment risks may increase. Thus, in leadership development, it is necessary not only to evaluate Extraversion but also to consider complementary traits such as Honesty–Humility and Agreeableness in a balanced manner. Overall, the results of this study indicate that applying the HEXACO model can provide a new framework for harassment prevention in workplaces. This approach opens up the possibility of preventive and scientific human resource management based on personality traits, in addition to the conventional reliance on behavioral observation and reactive responses.

Limitations

This study has several limitations. First, it was based on a cross-sectional design, and therefore the associations observed among HEXACO traits, Dark Triad traits, and harassment tendencies do not indicate causal relationships. For example, it cannot be determined whether low Honesty–Humility promotes harassment behaviors, or whether experiences of harassment influence personality traits. Second, the sample was recruited through crowdsourcing from the general adult population and does not necessarily represent employees in actual workplace environments. In particular, differences in workplace characteristics such as industry, job position, and organizational size, which may affect harassment tendencies, were not taken into account, limiting the external validity of the findings. Third, all measures used in this study were self-report questionnaires, which may be influenced by social desirability bias. Especially in the measurement of harassment tendencies, there is a possibility that respondents underreported unfavorable behaviors, meaning that the measures may not accurately reflect actual behavioral levels. Finally, the harassment measured in this study was based on self-perceptions of "tendencies" and did not directly observe behaviors in the workplace. Regarding this point, future research needs to verify the findings by incorporating colleague or supervisor evaluations, or by cross-referencing with actual cases of workplace harassment.

Future Directions

Based on the limitations of this study, several directions can be considered for future research. First, in order to clarify causal relationships, it is necessary to adopt longitudinal studies and experimental designs. For example, by tracking how changes in personality traits influence harassment behaviors over time, it would be possible to achieve more precise causal inferences. Second, to compensate for the limitations of self-report measures, it is desirable to collect multifaceted data that combine third-party evaluations and objective indicators. By incorporating evaluations from colleagues and supervisors, or actual records of workplace harassment cases, it is possible to reduce biases inherent in self-reports. Third, although this study targeted Japanese adults, cultural factors are highly likely to influence the associations between personality traits and harassment. Therefore, it is necessary in future research to distinguish between Japanese-specific characteristics and universal tendencies through cross-cultural comparisons. In particular, the emphasis on hierarchical relationships and the influence of gender norms are areas where cultural differences are pronounced, and international comparisons would be valuable both theoretically and practically. Finally, in addition to the HEXACO and Dark Triad traits examined in this study, incorporating Sadism from the Dark Tetrad, as well as positive traits such as altruism and empathy, would advance a more comprehensive understanding of harassment behaviors. Such extended research would contribute to bridging personality psychology and industrial–organizational psychology.

Conclusion

This study is characterized by its examination of the associations among HEXACO traits, Dark Triad traits, and workplace harassment tendencies in a sample of Japanese adults. The results revealed that Honesty–Humility consistently exerted a suppressive effect on both Dark Triad traits and harassment tendencies. Furthermore, traits such as Agreeableness and Openness were also identified as predictors of certain harassment behaviors, suggesting that the HEXACO model plays an important role in understanding interpersonal risks. On the other hand, Extraversion was positively associated with Narcissism and Psychopathy, indicating that personality traits do not always function in a purely adaptive manner. Moreover, the Dark Triad traits were significantly associated with harassment tendencies even in a Japanese sample, and since this finding is consistent with previous

studies in Western contexts, it suggests the existence of universal associations across cultures. At the same time, the gender effect observed in gender harassment indicates that Japan-specific socio-cultural factors may also be at play, highlighting the need for theoretical frameworks that take cultural contexts into account. Overall, this study demonstrates that personality assessment based on the HEXACO model can serve as an effective tool for harassment prevention and human resource management in workplace settings. In particular, the dimension of Honesty–Humility holds significant value for predicting risky behaviors that could not be fully captured by the traditional Big Five model. Therefore, in future research and practice, employing a comprehensive assessment framework that incorporates the HEXACO model could contribute to the prevention of harassment and the construction of healthier workplace environments.

Declarations

Conflict of Interest

The author declares that there are no financial or personal relationships with other people or organizations that could inappropriately influence (bias) this work. There are no conflicts of interest to declare.

Ethics Approval

The study was approved by the Institutional Review Board of the Public Health Research Foundation (Reference no. 25G0001). All procedures complied with relevant national and institutional ethical standards.

Informed Consent

Informed consent was obtained from all participants after providing clear information on the study purpose, procedures, privacy protection, voluntary participation and the right to withdraw, and dissemination of results. Data were collected anonymously, de-identified, and stored securely.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Authors' contributions

The author conceived and designed the study, collected and analyzed the data, wrote the manuscript, and approves the final version.

Acknowledgments

The author expresses sincere gratitude to all participants for their voluntary cooperation in completing the questionnaires. Appreciation is also extended to the Public Health Research Foundation's IRB for their review and approval.

Availability of data and material

(data transparency)

The de-identified dataset that supports the findings of this study is publicly available on GitHub at: https://github.com/etoki/paper/blob/main/harassment/raw.csv. The file harassment/raw.csv contains all variables used in the analysis. No personally identifying information is included; data were anonymized prior to sharing. Additional materials (e.g., variable descriptions or analysis notes) can be provided upon reasonable request to the corresponding author.

Model B = controls (age, gender, region) + Dark Triad (M, N, P) + HEXACO (H–H, E, X, A, C, O). Internal labels: B_controls+DT+HEXACO = Model B (overall); B_by_gender = Model B estimated separately by gender. Standardized β; HC3 robust SE; two-tailed tests; *** *p*<.001, ** *p*<.01, * *p*<.05.
